SPECIFIC GRAVITY

Factors Influencing Specific Gravity in Prince Edward Island Potato Production

Ryan Barrett, M.Sc, P.Ag
PEI Potato Board
Specific Gravity

• Tuber specific gravity refers to relative weight of tuber compared with the weight of the same volume of water.

• One of the most widely accepted measures of potato internal quality, because of its close relationship to tuber starch content and total solids.

• Tubers with low specific gravity require more time and oil for processing and tend to have darker fry color, whereas tubers with excessively high specific gravity are susceptible to increased bruising (Mosley and Chase 1993).

Winter Russet Burbank - Indexing
Crops: 14/15 - 15/16
Maximum Score = 100
Russet Burbank
Score ratio
Grav: 10 oz
1:##

[Graph showing data with labels and axes]
Gravity vs. 10 oz – Russet Burbank

• There are about a third of growers who are able to achieve decent bonus for both Specific Gravity and 10 oz.

• For remaining two-thirds, gravity and 10 oz fluctuate up and down, and appear to be somewhat antagonistic.

• The “downward trend” of 10 oz vs. specific gravity is not as great as thought, and is highly variable.
Winter Prospect - Indexing
Crops: 14/15 - 15/16
Maximum Score = 100
Gravity vs. 10 oz – Prospect

• Again, about a quarter to a third of growers are able to achieve decent bonus for both Specific Gravity and 10 oz.

• For remaining growers, it has appeared to be much easier to get 10 oz than gravity. Different relationship than Russet Burbank.

• Growers with high gravity scores don’t have lower average 10 oz scores.
Marketable Yield vs. Spec Grav – RB 2016

R² = 0.2881
Biological Reasons for Low Specific Gravity

• Low specific gravity (or low total solids) is a symptom of the tuber not being able to mature and senesce at the plant’s ideal rate.

• We know that some varieties naturally have higher specific gravities than others (i.e., Ranger Russet)

• Some factors influencing specific gravity are within the control of the grower, while others are largely outside of their control. Manage what can be managed!
Factors Impacting Specific Gravity

- Length of Growing Season
- Precipitation (Too Much/Too Little)
- Seed Quality and Planting Practices
- Pests and Diseases
- Top-killing/Tube Maturity at Harvest
- Fertility Program
Length of Growing Season

• To properly mature and senesce naturally, a variety must have the ability to complete its life cycle, the length of which varies by variety.

• Seed planted earlier, with more days of plant growth under increasing day length, is more likely to have higher specific gravity than seed planted late and forced to mature later into the fall.

• Early frosts can have a significant impact on gravity scores.
Water Effects

- Too much precipitation, particularly before harvest, can result in tubers becoming water-logged. Not only are these tubers at a higher risk of bacterial/fungal infection, they also generally have lower specific gravity.

- Potatoes under drought-stress during the growing season face limits to photosynthesis, decreasing production of starch. Lack of rainfall is of course a factor, but so are factors that reduce the water holding capacity of soil:
  - Low Soil Organic Matter
  - Soil Compaction
  - Aggregate Stability
Seed Quality and Planting Practices

- Small average seed size can impact the ability of the plant to quickly establish and develop, impacting specific gravity.

- Seed planted too close together or too far apart can have a detrimental impact on specific gravity. Important to know the physiological age of seed and recommended plant populations for the variety to optimize both yield and gravity.
Pests and Diseases

- **Defoliating insects** (ie. Colorado potato beetle) reduce the leaf area of the plant, limiting ability to photosynthesize.

- **Early Dying Complex** (Verticillium/root lesion nematodes) often causes premature senescence of potato plants, cutting short their natural life cycle and reducing gravity scores.
Top-Killing / Maturity at Harvest

• A number of studies over the years indicate that label rates of chemical vine dessication (Reglone/diquat) is associated with lower specific gravity scores.

• If plants die down too fast, they are unable to efficiently move sugars into the tubers and convert to starch.

• As well, water taken up by the plant’s root system following dessication moves to the tubers, reducing dry matter percentage.
Top-Killing / Maturity at Harvest

- Many Island growers now limit use of Reglone only when needed to ensure that tubers come off vines during harvest.

- Many growers using lower rates (0.25-0.35L/acre) to jump start senescence but not die down too quickly.
## Top-Killing / Maturity at Harvest

Fertility Program

Nitrogen

• Rates of N higher than required by the plant can lead to excessive vegetative growth. This extends the life cycle of the plant, delays natural senescence, and can lead to lower specific gravities.

• Only apply the amount of N required for your target yield, and consider split application of N or use of slow release N products.

Nitrogen Fertility Requirements for Commonly Grown Potato Varieties in Saskatchewan
Fertility Program

Phosphorus

- According to Laboski and Kelling, it appears that if soil test phosphorus (P) levels are low or very low, the addition of fertilizer P will usually increase tuber specific gravity.

- However, where soil test P levels were high or very high (such as the case in most PEI soils), additional P had relatively little impact on specific gravity.
Fertility Program

Potassium (K)

• Research trials both in PEI and elsewhere in North America have shown that excessive rates of muriate of potash (MOP or KCl) banded at planting can have a negative effect on specific gravity.

• Laboski and Kelling, 2007 say “this is mostly likely due to the osmotic effects of the increased tissue salt concentrations present with potassium chloride (KCl).”
Fertility Program

Potassium (K)

- Replacing KCl with K$_2$SO$_4$ or K-Mag in the planter blend has been shown by a number of growers to have a beneficial effect on specific gravity.

- KCl should ideally be applied either in the fall before potatoes or as a pre-plant fertilizer application, to allow the chlorine to leach out and reduce the salt effect.

Black Pond Farms

• Major factor influencing gravity scores for our farm is allowing the plants to mature and senesce as naturally as possible. This involved reducing the amount of Reglone used for vine killing.

• 2014 field trial. 3 split fields. Russet Burbank Not a great year for specific gravities.

Black Pond Farms

- Major Changes in Practice Resulting in Higher Gravities:
  - Limiting top-killing to one spray only
  - Reduction in the amount of banded Nitrogen
  - Fall application of 50% of total K needs for coming year

- Other changes having some effect:
  - Increasing crop available Mg
  - Limiting amount of MOP in planter blend
In last few years, our farm has struggled with below average specific gravity.

For 2017 growing season, we looked at making changes to our fertility program to try and improve specific gravity.

In 2017, reduced K in planter blend by 40 lbs/ac and replaced about half of MOP (KCl) with K-Mag

Also replaced AN primarily with Ammonium Sulfate

Summary

• There are many factors that impact specific gravity scores. Mother Nature has a large impact on gravity, but so do a number of management choices within the control of the grower.

• Above all, make choices that allow the crop to senesce as naturally as possible to maximize both yield and specific gravity.
Summary

• Factors affecting natural maturity & senescence:
  ✓ Early Planting
  ✓ Avoiding excess N rates
  ✓ Water holding capacity of soil (soil OM, compaction)
  ✓ Limit use of Reglone
Summary

• Limit use of KCl (MOP) in the planter blend.

✓ **Apply KCl in the fall before or early spring before planting to reduce salt impact.**

✓ **Replace KCl in the planter all or in part with K₂SO₄ (SOP) or K-Mag**
Thank You!
